## Advanced QE school: Hubbard and Koopmans functionals from linear response

# Carrier mobility and superconductivity with EPW

Hands-on Session (Tue.2)

Hands-on based on Quantum ESPRESSO (v7.2) and EPW v5.7 Tutorial based on the 2023 Virtual School on Many-Body Calculations using EPW and BerkeleyGW

# Introduction

In this tutorial, we will show in **Exercise 1** how to compute the intrinsic electron and hole low-field drift and Hall mobility of the polar cubic semiconductor BN using the linearised iterative Boltzmann transport equation (IBTE) and the self-energy relaxation time approximation (SERTA), with or without external magnetic field. In **Exercise 2** we will compute the superconducting properties of  $MgB_2$  by solving the anisotropic Migdal-Eliashberg equations.

For the description for all input flags please follow the link:

https://docs.epw-code.org/doc/Inputs.html

### Exercise 1

## 1.1 Theory

In this example we are going to calculate the drift and Hall hole carrier mobility of c-BN. The drift mobility is obtained with:

$$\mu_{\alpha\beta}^{d} = \frac{-1}{V^{uc} n^{c}} \sum_{n} \int \frac{\mathrm{d}^{3} k}{\Omega^{\mathrm{BZ}}} v_{n\mathbf{k}\alpha} \partial_{E_{\beta}} f_{n\mathbf{k}}$$
(1)

where the out of equilibrium occupations are obtained by solving the BTE:

$$\partial_{E_{\beta}} f_{n\mathbf{k}} = e v_{n\mathbf{k}\beta} \frac{\partial f_{n\mathbf{k}}^{0}}{\partial \varepsilon_{n\mathbf{k}}} \tau_{n\mathbf{k}} + \frac{2\pi \tau_{n\mathbf{k}}}{\hbar} \sum_{m\nu} \int \frac{\mathrm{d}^{3} q}{\Omega_{\mathrm{BZ}}} |g_{mn\nu}(\mathbf{k}, \mathbf{q})|^{2} \times \left[ (n_{\mathbf{q}\nu} + 1 - f_{n\mathbf{k}}^{0}) \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} + \hbar \omega_{\mathbf{q}\nu}) + (n_{\mathbf{q}\nu} + f_{n\mathbf{k}}^{0}) \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} - \hbar \omega_{\mathbf{q}\nu}) \right] \partial_{E_{\beta}} f_{m\mathbf{k}+\mathbf{q}}.$$
 (2)

The scattering rate in Eq. (2) is defined as:

$$\tau_{n\mathbf{k}}^{-1} \equiv \frac{2\pi}{\hbar} \sum_{m\nu} \int \frac{d^3q}{\Omega_{\rm BZ}} |g_{mn\nu}(\mathbf{k}, \mathbf{q})|^2 \left[ (n_{\mathbf{q}\nu} + 1 - f_{m\mathbf{k}+\mathbf{q}}^0) \right] \times \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} - \hbar\omega_{\mathbf{q}\nu}) + (n_{\mathbf{q}\nu} + f_{m\mathbf{k}+\mathbf{q}}^0) \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} + \hbar\omega_{\mathbf{q}\nu}).$$
(3)

A common approximation to Eq. (2) is called the self-energy relaxation time approximation (SERTA) and consists in neglecting the second term in the right-hand of the equation which gives:

$$\mu_{\alpha\beta}^{\text{SERTA}} = \frac{-e}{V^{\text{uc}} n^{\text{c}}} \sum_{n} \int \frac{\mathrm{d}^{3} k}{\Omega^{\text{BZ}}} \frac{\partial f_{n\mathbf{k}}^{0}}{\partial \varepsilon_{n\mathbf{k}}} v_{n\mathbf{k}\alpha} v_{n\mathbf{k}\beta} \tau_{n\mathbf{k}}.$$
 (4)

The the low-field phonon-limited carrier mobility in the presence of a small finite magnetic field **B** is given by:

$$\mu_{\alpha\beta}(B_{\gamma}) = \frac{-1}{V^{\text{uc}}n^{\text{c}}} \sum_{n} \int \frac{\mathrm{d}^{3}k}{\Omega^{\text{BZ}}} v_{n\mathbf{k}\alpha} [\partial_{E_{\beta}} f_{n\mathbf{k}}(B_{\gamma}) - \partial_{E_{\beta}} f_{n\mathbf{k}}], \tag{5}$$

again solving the BTE with finite (small) magnetic field:

$$\left[1 - \frac{e}{\hbar} \tau_{n\mathbf{k}} (\mathbf{v}_{n\mathbf{k}} \times \mathbf{B}) \cdot \nabla_{\mathbf{k}}\right] \partial_{E_{\beta}} f_{n\mathbf{k}}(B_{\gamma}) = e v_{n\mathbf{k}\beta} \frac{\partial f_{n\mathbf{k}}^{0}}{\partial \varepsilon_{n\mathbf{k}}} \tau_{n\mathbf{k}} + \frac{2\pi \tau_{n\mathbf{k}}}{\hbar} \sum_{m\nu} \int \frac{\mathrm{d}^{3} q}{\Omega^{\mathrm{BZ}}} |g_{mn\nu}(\mathbf{k}, \mathbf{q})|^{2} \\
\times \left[ (n_{\mathbf{q}\nu} + 1 - f_{n\mathbf{k}}^{0}) \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} + \hbar \omega_{\mathbf{q}\nu}) + (n_{\mathbf{q}\nu} + f_{n\mathbf{k}}^{0}) \delta(\varepsilon_{n\mathbf{k}} - \varepsilon_{m\mathbf{k}+\mathbf{q}} - \hbar \omega_{\mathbf{q}\nu}) \right] \partial_{E_{\beta}} f_{m\mathbf{k}+\mathbf{q}}(B_{\gamma}). \quad (6)$$

The Hall factor and Hall mobility are then obtained as:

$$r_{\alpha\beta}(\hat{\mathbf{B}}) \equiv \lim_{\mathbf{B} \to 0} \sum_{\delta \epsilon} \frac{[\mu_{\alpha\delta}^{\mathrm{d}}]^{-1} \, \mu_{\delta\epsilon}(\mathbf{B}) \, [\mu_{\epsilon\beta}^{\mathrm{d}}]^{-1}}{|\mathbf{B}|} \tag{7}$$

$$\mu_{\alpha\beta}^{\text{Hall}}(\hat{\mathbf{B}}) = \sum_{\gamma} \mu_{\alpha\gamma}^{\text{d}} r_{\gamma\beta}(\hat{\mathbf{B}}), \tag{8}$$

where  $\hat{\mathbf{B}}$  is the direction of the magnetic field. More information can be found in the review Rep. Prog. Phys. **83**, 036501 (2020).

lonized impurity scattering is an important mobility limiting mechanism alongside thermal lattice vibrations in doped materials or materials with native ionized point defects. For 3D bulk crystals containing randomly distributed ionized impurities, we can exploit the Kohn-Luttinger ensemble average to obtain the partial transition rates of carriers by the ionized impurities.

$$\tau_{n\mathbf{k}\to m, \mathbf{k}+\mathbf{q}}^{-1, ii} = n_{ii} \frac{2\pi}{\hbar} \left[ \frac{e^2}{4\pi\varepsilon_0} \frac{4\pi Z}{\Omega_{\mathbf{u.c}}} \right]^2 \sum_{\mathbf{G}\neq -\mathbf{q}} \frac{|\langle u_{m\mathbf{k}+\mathbf{q}}| e^{i\mathbf{G}\cdot\mathbf{r}} | u_{n\mathbf{k}} \rangle_{\mathbf{u.c}}|^2}{|(\mathbf{q}+\mathbf{G})\cdot\varepsilon^0\cdot(\mathbf{q}+\mathbf{G})|^2} \delta(\epsilon_{n\mathbf{k}} - \epsilon_{m\mathbf{k}+\mathbf{q}}), \tag{9}$$

Here,  $n_{ii}$  is the concentration of ionized impurities in the system, Z is the charge of the ionized impurities, and  $\varepsilon^0$  is the low-frequency dielectric tensor which includes contributions from both electronic and ionic polarizability. More information can be found in the article Phys. Rev. B **107**, 125207 (2023).

## 1.2 Preliminary calculations with Quantum Espresso

First download the exercise files:

```
$ wget https://github.com/materialscloud-org/QuantumESPRESSO-school-2023/tree/main/Day2/Day2.Ponce.tar
$ tar -xvf Day2.Ponce.tar
$ cd exercise1/
```

► Make a self-consistent calculation for c-BN.

```
calculation = 'scf'
prefix = 'bn'
restart_mode = 'from_scratch'
pseudo_dir = './'
outdir = './'
/
```

```
&system
   ibrav
                  = 2
   celldm(1)
                  = 6.833
                  = 2
   nat
                   = 2
                   = 40
   ecutwfc
   diagonalization = 'david'
                  = 0.7
   mixing_beta
   conv_thr
                  = 1.0d-13
ATOMIC_SPECIES
 B 10.811 B-PBE.upf
 N 14.0067 N-PBE.upf
ATOMIC_POSITIONS {crystal}
B 0.00 0.00 0.00
   -0.25 0.75 -0.25
K_POINTS automatic
8 8 8 0 0 0
```

**Note**: In practice the **k**-point grid needs to be fairly large in order to get converged dielectric function and Born effective charges during the following phonon calculation.

```
$ mpirun -np 2 pw.x -in scf.in | tee scf.out
```

► Compute the vibrational properties of c-BN on a coarse 4x4x4 q-point grid.

```
--
&inputph
    tr2_ph=1.0d-17,
    prefix='bn',
    amass(1)=10.811,
    amass(2)=14.0067,
    outdir='./',
    fildyn='bn.dyn.xml',
    fildvscf='dvscf'
    ldisp=.true.,
    epsil=.true.,
    nq1 = 4,
    nq2 = 4,
    nq3 = 4
/
```

**Note**: We have the input variable <code>epsil=.true</code>. which computes the macroscopic dielectric constant in non-metallic systems. If you add .xml after the name of the dynamical matrix file, it will produce the data in XML format (preferred). **Note 2**: The input variable responsible to produce the electron-phonon matrix element is <code>fildvscf</code>. Always make sure that this variable is present.

**Note 3**: Notice the very tight tr2\_ph threshold parameter on the self-consistent first-order perturbed wavefunction. This is crucial to obtain good vibrational properties.

```
$ mpirun -np 2 ph.x -in ph.in | tee ph.out
```

The calculation should take about 5 min on 4 cores. During the run, notice the IBZ q-point grid:

```
Dynamical matrices for (4, 4, 4) uniform grid of q-points

                                   1.89277 )
   atom
          2 N Mean Z*: -1.89277
         -1.89277
                  0.0000
                                  0.00000)
E*x (
         0.00000
E*y (
                      -1.89277
                                   0.00000)
E*z (
          -0.00000
                      0.00000
                                   -1.89277)
```

The experimental dielectric constant in c-BN is about 4.46. More accurate values can be obtained with larger k-point grids. c-BN is a polar material and has a Born effective charge of 1.89 which is very close to theoretical value of 1.91.

Finally, we need to post-process some of the data to make it ready for EPW. To do so, we can use a python script (usually provided in QE/EPW/bin/pp.py but copied here for convenience).

▶ Run the python post-processing to create the save folder

```
$ python3 pp.py
```

The script will ask you to enter the prefix used for the calculation. In this case enter "bn". The script will create a new folder called "save" that contains the dvscf potential files, pattern files, and dynamical matrices on the IBZ.

▶ Compute the low-frequency dielectric constant including ionic polarization for c-BN.

We need one final ingredient before moving on to running EPW if we intend to examine ionized impurity scattering, and that is to determine the zone-center dielectric polarizability of c-BN including ionic polarization. We have the electronic contribution from ph.x, but we will use dynmat.x to determine  $\varepsilon^0$ . Below is input for dynmat.x, dynmat.in.

```
dynmat.in

&input
fildyn='bn.dyn1.xml',
amass(1)=10.811,
amass(2)=14.0067,
asr='simple',
lperm=.true. ! calculate ionic polarizability
filout='bn.dynmat.out',
fileig='bn.eig'
/
```

To do this, run:

\$ dynmat.x -in dynmat.in | tee dynmat.out

We can find the following lines in the dynmat.out file:

```
Electronic dielectric permittivity tensor (F/m units)
4.597197 0.000000 0.000000
-0.000000 4.597197 -0.000000
0.000000 0.000000 4.597197

... with zone-center polar mode contributions
6.629671 0.000000 -0.000000
0.000000 6.629671 -0.000000
-0.000000 -0.000000 6.629671
```

We will need the value of  $\approx 6.63$  for  $\epsilon_0$  to include ionized impurity scattering later on.

# 1.3 Interpolation of the electron-phonon matrix element in real-space with EPW

▶ Do a non self-consistent calculation on a 4x4x4 uniform and  $\Gamma$ -centered k-point grid with crystal coordinates in the interval [0,1[

Such a grid can be for example generated with the wannier90 utility with kmesh.pl 4 4 4. The nscf.in file is as follow:

```
nscf.in
&control
   calculation
                   = 'nscf'
                   = 'bn'
   prefix
   restart_mode = 'from_scratch'
   pseudo_dir
   outdir
                    = './'
&system
                   = 2
   ibrav
    celldm(1)
                   = 6.833
                   = 2
   nat
                   = 2
   ntyp
   ecutwfc
                   = 40
                    = 20
   nbnd
&electrons
   diagonalization = 'david'
   mixing_beta = 0.7
                   = 1.0d-13
   conv_thr
ATOMIC_SPECIES
 B 10.811 B-PBE.upf
N 14.0067 N-PBE.upf
ATOMIC_POSITIONS {crystal}
   0.00 0.00 0.00
-0.25 0.75 -0.25
N
K_POINTS crystal
 0.00000000 0.00000000 0.00000000 1.562500e-02
 0.00000000 0.00000000 0.25000000 1.562500e-02
 0.00000000 0.00000000 0.50000000 1.562500e-02
```

\$ mpirun -np 2 pw.x -in nscf.in | tee nscf.out

The reason for the non-self consistent calculation is that EPW needs the wavefunctions on the full BZ on a grid between 0 and 1.

**Note**: Since we are also interested in electron mobility, we will need the conduction bands. Notice that we added the input nbnd = 20 in nscf.in

▶ Perform an EPW calculation to Fourier-transform the electron-phonon matrix element from a coarse 4x4x4 k and q-point grids to real space and then interpolate the electronic band structure and phononic dispersion along the  $L - \Gamma - X - K - \Gamma$  high symmetry line by reading the file LGXKG.txt.

```

              = 4
  nq3
```

```
$ mpirun -np 2 epw.x -npool 2 -input epw1.in | tee epw1.out
```

**Note**: The number of pool -npool has to be the same as the total number of core -np since **k**-point parallelization is (almost) the only parallelization level allowed. **G**-vector parallelization will be introduced in EPW v6.0.

The calculation should take less than 2 min. Note that the code should have detected the presence of the quadrupole.fmt file and correctly read the quadrupole tensor. Look in the output for the line Quadrupole tensor is correctly read:. In this hands-on we will not cover how to obtain the quadrupole tensor and they are simply given here. There are two ways to obtain them:

- Using perturbation theory. This is implemented in a recent version of the Abinit software.
- Fitting the perturbed density or the electron-phonon matrix elements in the long wavelength limit obtained by direct DFPT calculations.

More information can be found in Phys. Rev. Research 3, 043022 (2021)

At the end of the calculation, because of the keyword band\_plot = .true., the code should produce the band.eig and phband.freq files that contain the electronic band structure and phononic dispersion along a path given in the filkf and filqf files.

If you want to have files in an easy gnuplot format, you can use the plotband.x tool by doing

\$ plotband.x

and follow the instructions. You should check that both plots look reasonable.

- ▶ Do a restart calculation (restarting from the bn.epmatwp1 file) and compute the hole mobility of c-BN.
- \$ mpirun -np 2 epw.x -npool 2 -input epw2.in | tee epw2.out

The input file is as follow:

```
epw2.in
&inputepw
            = 'bn'
prefix
            = './'
outdir
elph
            = .true.

```

#### Notes:

- The value of fermi\_energy was obtained from the output of the previous calculation epw1.in
- epwread allows for the restart from the bn.epmatwp1 file
- int\_mob allows to perform both electron and hole calculations at the same time but is not recommanded.
- carrier and noarrier define the carrier concentration. If carrier = .true. then the intrinsic mobility with noarrier concentration (in cm $^{-3}$ ) is computed. If noarrier is positive it will compute the electron mobility and if it is negative it will compute the hole mobility. The resulting mobility should be independent of the choice of carrier concentration in reasonable ranges  $10^{10}$   $10^{16}$  cm $^{-3}$ .
- iterative\_bte asks for the iterative solution of the BTE in addition to SERTA.
- nstemp and temps define the lattice temperature at which the mobility is evaluated.
- restart and restart\_step will create restart point every (in this case) 1000 q-points. You can try breaking the run after a restart point and restart to test this feature.
- bfieldz adds a (small) finite magnetic field along the Cartesian z direction (in unit of Tesla). This will automatically trigger the calculation of the Hall factor.
- mob\_maxiter is the maximum number of iterations for the BTE solution.
- degaussw = 0.0 means that adaptive smearing is used. Positive values give Gaussian smearing.

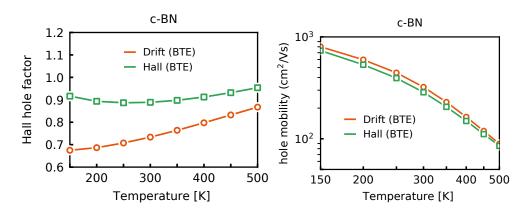

The run should take about 4 min. The fine k and q point grids need to be much denser for real calculations. However, we can already get relatively decent results.

▶ Re-run the code with multiple temperatures (using nstemp = 4 and temps = 100, 200, 400, 500). You should remove the restart.fmt file before doing so.

Try filling the table below for the hole mobility:

T (K)	hole $\varepsilon_F$ (eV)	drift SERTA $\mu$ (cm $^2$ /Vs)	drift BTE $\mu$ (cm $^2$ /Vs)	Hall BTE $\mu$ (cm $^2$ /Vs)
100				
200				
300				
400				
500				

At convergence you should get 1:

where the room temperature values with SOC should be around 319  $cm^2/Vs$  for the drift BTE and 281  $cm^2/Vs$  for the Hall mobility with a Hall factor of 0.88.

- ▶ Try to increase the fine grids and add a few more temperatures and see if you can get a result closer to convergence.
- ► Try adding SOC
- ▶ Try removing or renaming the file quadrupole.fmt to do the interpolation with dipole only and see the impact on the results.

#### 1.4 Compute the spectral decomposition

- ▶ Do a restart calculation (restarting from the bn.epmatwp1 file) and compute the hole spectral decomposition of c-BN.
- ▶ You should remove the restart.fmt file.

\$ mpirun -np 2 epw.x -npool 2 -input epw3.in | tee epw3.out

The input file is as follow (we show only the difference wrt epw2.in):

```
--
&inputepw

iverbosity = 3
mob_maxfreq = 160
```

<sup>&</sup>lt;sup>1</sup>The figure is from Phys. Rev. Research 3, 043022 (2021)

```
mob_nfreq = 640 ! To have 0.25 meV intervals

nkf1 = 60
nkf2 = 60
nkf3 = 60
nqf1 = 60
nqf2 = 60
nqf3 = 60
/
```

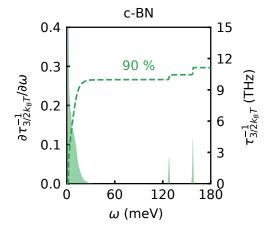

At the end of the calculation, the code should have produced a file named inv\_tau\_freq.fmt. You should open the file and look for the maximum number of **k**-points within the fsthick, here you should have 272. You should also look for the number of bands, here you should find 3.

► Edit the gaussian-h.py python script to correspond to the calculation you have been doing. Then run it.

\$ python3 gaussian-h.py

The script should produce a file named inv\_tau\_freq.fmt-gaussian1.0 which you can plot with your favorite software. Note that the results are not converged but it should be clear that acoustic scattering is dominating in c-BN.

At convergence you should get <sup>2</sup>:

## 1.5 Include carrier-ionized impurity scattering

- ▶ You will now run a calculations that includes the influence of ionized impurity scattering on the hole mobility of c-BN.
- ► You should once again remove the restart.fmt file:

\$ rm restart.fmt

Then, run EPW:

\$ mpirun -np 2 epw.x -npool 2 -input epw4.in | tee epw4.out

The input file for epw4.in is as follow (we show only the difference wrt epw2.in):

<sup>&</sup>lt;sup>2</sup>The figure is from Phys. Rev. Research 3, 043022 (2021)

```
--
&inputepw

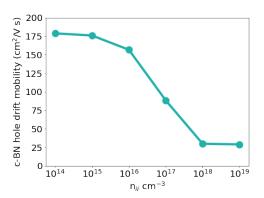

ncarrier = -1E17 ! absolute value MUST match ii_n, negative sign for holes.

ii_g = .true.
ii_charge = 1.0d0
ii_n = 1.0d17 ! must match ncarrier, keep positive for both holes and electrons
ii_scattering = .true.
ii_only = .false.
ii_eps0 = 6.62967d0
/
```

#### Notes:

- ii\_g = .true. tells EPW to calculate ionized impurity matrix elements
- ii\_charge is the charge of the ionized impurities in units of the electron charge.
- ii.n is the density of ionized impurities in units of cm $^{-3}$ . For bulk, typical doping values range from  $10^{15}$  to  $10^{18}$  cm $^{-3}$ , higher would result in degenerate doping.
- ii\_scattering = .true. tells EPW to compute the ionized impurity scattering rates.
- ii\_only: if ii\_only were set to .true., this would tell EPW to only include ionized impurity scattering and omit phonon scattering. Since we want phonon and ionized impurity scattering, we set ii\_only = .false..
- ii\_eps0 is the low-frequency dielectric constant, determined by dynmat.x.

After running epw.x with input epw4.in, we should find a hole mobility at 300 K of  $88.25 \text{ cm}^2/\text{V}$  s, reduced from a phonon-only limited mobility of  $178.87 \text{ cm}^2/\text{V}$  s previously calculated. The presence of ionized impurities strongly influences the drift mobilities. As an exercise, you can modify ii\_n (and ncarrier accordingly), between 1.0d15 and 1.0d19 to see how the hole mobility at 300 K changes as the concentration of ionized impurities increases. Here is the plot of the expected results for this example.

NOTE: Ionized impurity scattering and Hall mobilities have not been tested together. The use of the ionized impurity functionality in EPW should be currently limited to drift mobilities only.

#### Exercise 2

In this tutorial we are going to calculate the superconducting properties of  $MgB_2$  by solving the anisotropic Migdal-Eliashberg equations. The theory related to this tutorial can be found in the Phys. Rev. B **87**, 024505 (2013).

For this exercise, you will need sufficient RAM memory (>2 Gb). Make sure your VM has enough and restart if needed.

Go to exercise2:

- \$ cd ../exercise2
- ▶ 1st step: Run a self-consistent calculation on a homogeneous 12x12x12 k-point grid and a phonon calculation on a homogeneous 3x3x3 q-point grid using the following jobscript (job.ph) and input files (scf.in and ph.in) for MgB<sub>2</sub>:

Note: The smearing is quite large in order to get reasonable values in subsequent calculations.

```
$ cd phonon
$ mpirun -np 2 pw.x -in scf.in | tee scf.out
$ mpirun -np 2 ph.x -in ph.in | tee ph.out
```

     0.333333333 0.577350269
                              0.291867841
```

- ▶ 2nd step: Gather the .dyn, .dvscf, and patterns files into a new save directory using the pp.py python script.
- \$ python3 pp.py

The script will ask you to provide the prefix of your calculation (here "mgb2").

▶ 3rd step: Do a non self-consistent calculation on a  $6\times6\times6$  uniform and  $\Gamma$ -centered grid between [0,1] in crystal coordinates and an EPW calculation for the anisotropic superconducting properties using the jollowing jobscript (job.epw1) and input files (nscf.in and epw1.in):

```
$ cd ../epw1-FSR
$ mpirun -np 2 pw.x -in scf.in | tee scf.out
$ mpirun -np 2 pw.x -in nscf.in | tee nscf.out
$ mpirun -np 2 epw.x -npool 2 -in epw1.in | tee epw1.out
```

Note 1: The homogeneous k grid for the non self-consistent calculations can be generated using the script kmesh.pl \$ ./kmesh.pl 6 6 6

**Note 2**: A non self-consistent calculation requires the charge density found from a previous self-consistent run with pw.x. In the jobscript job.epw1 you can see that a self-consistent calculation is run first with the same scf.in file used in the phonon directory. Alternatively, one can make the mgb2.save directory and copy there the files from phonon/mgb2.save.

**Note 3**: EPW calculations with ephwrite = .true. require that the fine k or q grids are commensurate, i.e., nkf1, nkf2, nkf3 to be multiple of nqf1, nqf2, nqf3.

Note 4: The Migdal-Eliashberg equations are solved in the standard, Fermi surface restriction (FSR), approximation.

• Calculate the isotropic and anisotropic electron-phonon coupling strength by setting the keywords eliashberg = .true. in the EPW input file.

The anisotropic electron-phonon coupling strength takes the following form:

$$\lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_j) = N_F \sum_{\nu} \frac{2\omega_{\mathbf{q}\nu}}{\omega_j^2 + \omega_{\mathbf{q}\nu}^2} |g_{mn\nu}(\mathbf{k},\mathbf{q})|^2$$
(10)

The band- and wavevectron-dependent electron-phonon coupling strength  $\lambda_{n\mathbf{k}}(\omega_j)$  is defined as:

$$\lambda_{n\mathbf{k}}(\omega_j) = \sum_{m} \int \frac{d\mathbf{q}}{\Omega_{\text{BZ}}} \frac{\delta(\epsilon_{m\mathbf{k}+\mathbf{q}} - \epsilon_{\text{F}})}{N_{\text{F}}} \lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_j)$$
 (11)

The isotropic electron-phonon coupling strength takes the form:

$$\lambda(\omega_j) = \sum_{n} \int \frac{d\mathbf{k}}{\Omega_{\rm BZ}} \frac{\delta(\epsilon_{n\mathbf{k}} - \epsilon_{\rm F})}{N_{\rm F}} \lambda_{n\mathbf{k}}(\omega_j)$$
 (12)

The standard electron-phonon coupling strength  $\lambda$  found in the literature corresponds to setting  $\omega_i=0$  in Eq. (12).

The isotropic Eliashberg spectral function takes the following form:

$$\alpha^{2} F(\omega) = \frac{1}{N_{\rm F}} \sum_{nm\nu} \int \frac{d\mathbf{k}}{\Omega_{\rm BZ}} \int \frac{d\mathbf{q}}{\Omega_{\rm BZ}} |g_{mn\nu}(\mathbf{k}, \mathbf{q})|^{2} \delta(\omega - \omega_{\mathbf{q}\nu}) \delta(\epsilon_{n\mathbf{k}} - \epsilon_{\rm F}) \delta(\epsilon_{m\mathbf{k}+\mathbf{q}} - \epsilon_{\rm F})$$
(13)

• Solve the anisotropic FSR Migdal-Eliashberg equations on the imaginary frequency axis by setting the keywords eliashberg = .true., laniso = .true., and limag = .true. in the EPW input file. The equations are solved self-consistently for each temperature value specified in the input file. The calculation at each temperature ends when either the converge threshold (conv\_thr\_iaxis) or the maximum number of iterations (nsiter) is reached.

**Note 1**: If at a specific temperature the maximum number of iterations is reached without achieving convergence, the code will stop and not move to the next temperature in the list.

**Note 2**: Because the electron-phonon matrix elements do not depend on the temperature at which the Migdal-Eliashberg equations are solved, they can be reused in subsequent EPW calculations at different temperatures. This is the reason why ephmatXX files are saved in the mgb2.ephmat directory. The anisotropic FSR Migdal-Eliashberg equations take the following form:

$$Z_{n\mathbf{k}}(i\omega_{j}) = 1 + \frac{\pi T}{\omega_{j} N_{F}} \sum_{mj'} \int \frac{d\mathbf{q}}{\Omega_{BZ}} \frac{\omega_{j'}}{\sqrt{\omega_{j'}^{2} + \Delta_{m\mathbf{k}+\mathbf{q}}^{2}(i\omega_{j'})}} \times \lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_{j} - \omega_{j'}) \delta(\epsilon_{m\mathbf{k}+\mathbf{q}} - \epsilon_{F})$$

$$Z_{n\mathbf{k}}(i\omega_{j})\Delta_{n\mathbf{k}}(i\omega_{j}) = \frac{\pi T}{N_{F}} \sum_{mj'} \int \frac{d\mathbf{q}}{\Omega_{BZ}} \frac{\Delta_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})}{\sqrt{\omega_{j'}^{2} + \Delta_{m\mathbf{k}+\mathbf{q}}^{2}(i\omega_{j'})}} \times \left[\lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_{j} - \omega_{j'}) - \mu_{c}^{*}\right] \delta(\epsilon_{m\mathbf{k}+\mathbf{q}} - \epsilon_{F}), \tag{14}$$

where  $\lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_j - \omega_{j'})$  is the anisotropic electron-phonon coupling strength. The semiempirical Coulomb parameter  $\mu_c^*$  is provided as an input varible  $\underline{\mathtt{muc}}$  in the EPW calculation.

The calculation of superconducting properties will be accompanied by significant I/O. In the following we will describe various physical quantities saved in the output files and how to process them. We will use XX in the name of the output files to indicate the temperature at which the equations are solved.

▶ 4th step: Plot the isotropic and anisotropic electron-phonon coupling strength.

mgb2.lambda\_pairs, mgb2.lambda\_k\_pairs, and mgb2.a2f files are generated by setting eliashberg = .true.

mgb2.lambda\_pairs file contains the anisotropic electron-phonon coupling strength  $\lambda_{n\mathbf{q},m\mathbf{k}pq}(0)$  on the Fermi surface.

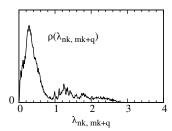

mgb2.lambda\_k\_pairs file contains the band- and wavevector-dependent anisotropic electron-phonon coupling strength  $\lambda_{n\mathbf{k}}(0)$  on the Fermi surface.

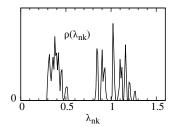

mgb2.a2f file contains the isotropic Eliashberg spectral function  $\alpha^2 F(\omega)$  and cumulative electron-phonon coupling strength as a function of frequency  $\omega$  (meV) for different phonon smearing values (see the end of the file for information about the smearing).

Note: First, put # in front of the 1st line and the last 7 lines of mgb2.a2f, otherwise gnuplot does not work.

You can use the gnuplot script fig5.plt to plot. You should get something similar to Fig. 1.

```
$ gnuplot fig5.plt
$ evince fig5.pdf
```

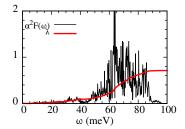

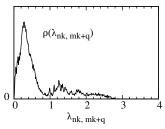

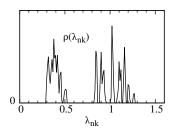

Fig. 5 Left: The anisotropic electron-phonon coupling strength  $\lambda_{n\mathbf{q},m\mathbf{k}pq}(0)$  (from mgb2.lambda\_pairs). Middle: The anisotropic electron-phonon coupling strength  $\lambda_{n\mathbf{k}}(0)$  on the Fermi surface (from mgb2.lambda\_k\_pairs). Right: The isotropic Eliashberg spectral function  $\alpha^2 F(\omega)$  (columns 1:2 from mgb2.a2f) and integrated electron-phonon coupling strength  $\lambda$  (columns 1:12 from mgb2.a2f).

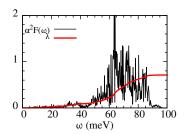

Fig. 6 At convergence you should get something close to this figure (see Phys. Rev. B **87**, 024505 (2013) for fully converged calculation parameters).

▶ 5th step: Plot the superconducting gap along the imaginary frequency axis and the real frequency axis.

mgb2.imag\_aniso\_XX files are generated by setting eliashberg = .true., laniso = .true., and limag = .true. Each file contains 4 columns: the frequency  $i\omega_j$  (eV) along the imaginary axis, the Kohn-Sham eigenvalue  $\epsilon_{n\mathbf{k}}$  (eV) relative to the Fermi level, the quasiparticle renormalization  $Z_{n\mathbf{k}}(i\omega_j)$ , and the superconducting gap  $\Delta_{n\mathbf{k}}(i\omega_j)$  (eV).

mgb2.pade\_aniso\_XX files are generated by setting lpade = .true.. Each file contains 6 columns: the energy  $\omega$  (eV) along the real axis, the Kohn-Sham eigenvalue  $\epsilon_{n\mathbf{k}}$  (eV) relative to the Fermi level, the real part of the quasiparticle renormalization  $\mathrm{Re}Z_{n\mathbf{k}}(\omega)$ , the imaginary part of the quasiparticle renormalization  $\mathrm{Im}Z_{n\mathbf{k}}(\omega)$ , the real part of the superconducting gap  $\mathrm{Re}\Delta_{n\mathbf{k}}(\omega)$  (eV), and the imaginary part of the superconducting gap  $\mathrm{Im}\Delta_{n\mathbf{k}}(\omega)$  (eV).

mgb2.acon\_aniso\_XX files could also be generated by setting lacon = .true.. These files will contain similar information as mgb2.pade\_aniso\_XX.

You can use the gnuplot script fig7.plt to plot. You should get something similar to Fig. 3 at 10 K. The file fig7.pdf is too large (10MB) to open while connecting to a remote server: To avoid opening it directly, you can use pdftopng command to show the plot.

- \$ gnuplot fig7.plt
- \$ pdftopng fig7.pdf fig7
- \$ display fig7-000001.png

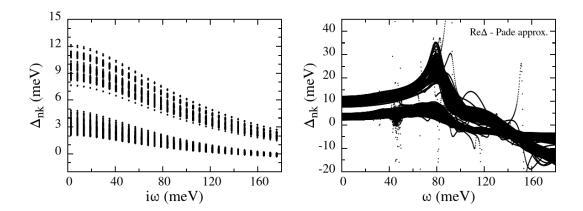

Fig. 7 Left: Superconducting gap along the imaginary axis (columns 1:4 from mgb2.imag\_aniso\_010.00). Right: Superconducting gap along the real axis (columns 1:5 from mgb2.pade\_aniso\_010.00 - this file is about 70MB).

The fine  ${\bf k}$  and  ${\bf q}$  point grids need to be much denser for real calculations. At convergence you should get:

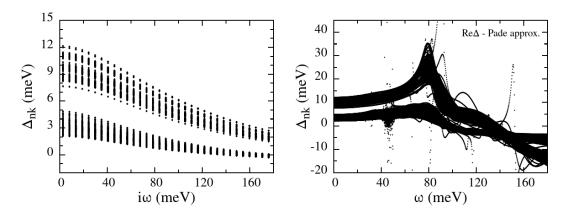

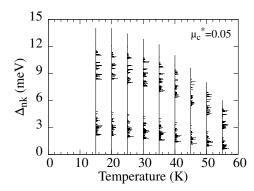

Fig. 8 At convergence you should get something close to this figure (see Phys. Rev. B **87**, 024505 (2013) for fully converged calculation parameters). (Note: Only about half of the points are shown.)

▶ 6th step: Plot the leading edge of the superconducting gap as a function of temperature.

You should get the following graph by plotting the data from all mgb2.imag\_aniso\_gap0\_XX files. Use the gnuplot script fig9.plt.

- \$ gnuplot fig9.plt
- \$ evince fig9.pdf

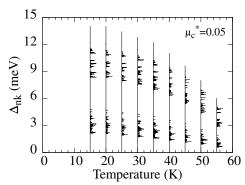

Fig. 9 Calculated anisotropic superconducting gap of  $MgB_2$  on the Fermi surface as a function of temperature. At convergence you should get the right hand-side figure (see Phys. Rev. B **87**, 024505 (2013) for fully converged calculation parameters). (Note: the heights of the histograms are multiplied by a factor of 2 while plotting for visibility.)

▶ 7th step: Plot the superconducting quasiparticle density of states.

The quasiparticle density of states (DOS) in the superconducting state relative to the DOS in the normal state is given by:

$$\frac{N_S(\omega)}{N_F} = \sum_{n} \int \frac{d\mathbf{k}}{\Omega_{BZ}} \frac{\delta(\epsilon_{n\mathbf{k}} - \epsilon_F)}{N_F} \operatorname{Re} \left[ \omega / \sqrt{\omega^2 - \Delta_{n\mathbf{k}}^2(\omega)} \right]$$
(15)

mgb2.qdos\_XX files contain the quasiparticle density of states in the superconducting state relative to the density of states in the normal state  $N_S(\omega)/N_{\rm F}$  as a function of frequency (eV) at various XX temperatures.

You can use the gnuplot script fig10.plt to plot mgb2.qdos\_010.00. Edit fig10.plt to add the value of DOS in the normal state and run gnuplot.

```
fig10.plt
set terminal pdfcairo color dashed enhanced font "Times,25" fontscale 0.4 size 4,3 lw 2
...
set xrange [0:15]
set yrange [0:2.2]
set out "fig10.pdf"
set key at graph 0.9, 0.9
NF= 0.324589885287221  # DOS in the normal state
plot "mgb2.qdos_010.00" u ($1*1000):($2/NF) w l lw 2 lt 1 lc rgb "black" notitle
reset
```

```
$ gnuplot fig10.plt
$ evince fig10.pdf
```

You should get something similar to Fig. 6 (left) at 10 K:

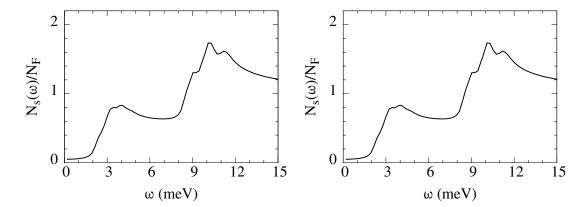

Fig. 10 Calculated  $N_S(\omega)/N_{\rm F}$  as a function of frequency at 10 K. At convergence you should get something closer to the right hand-side figure (see Phys. Rev. B **87**, 024505 (2013) for fully converged calculation parameters). (Note: the second column of mgb2.qdos\_XX should be divided by the value of DOS from the epw1.out).

- ▶ 8th step: (Optional due to time limit) Try to increase the fine grids and see if you can get a result closer to convergence. Note that if either k or q is changed you need to obtain new ephmatXX, egnv, freq, and ikmap files (saved in the mgb2.ephmat directory).
- ▶ 9th step: (Optional due to time limit) Check the effect of the Coulomb pseudopotential  $\mu_c^*$  on the superconducting gap and the critical temperature by varying the input variable muc. For this step you can re-use the files saved in the mgb2.ephmat directory.
- ▶ 10th step: Solve the anisotropic full-bandwidth (FBW) Migdal-Eliashberg equations. The self-consistent and non self-consistent calculations are the same as for the standard FSR approximation, you can either copy the '../epw1-FSR/mgb2.save' directory or rerun the self-consistent and non self-consistent calculations. After this, do an EPW calculation using the following jobscript (job.epw2) and input file (epw2.in; only differences with respect to ../epw1-FSR/epw1.in file are shown below):

**Note**: Here, we have fixed the chemical potential at the Fermi level. If you want to update the chemical potential at every temperature, set muchem = .true. in your EPW input file.

```
$ cd ../epw2-FBW
$ mpirun -np 2 pw.x -in scf.in | tee scf.out
$ mpirun -np 2 pw.x -in nscf.in | tee nscf.out
$ mpirun -np 2 epw.x -npool 2 -in epw2.in | tee epw2.out
```

```
--
fbw = .true.
```

The anisotropic FBW Migdal-Eliashberg equations are solved self-consistently on the imaginary frequency axis by setting the keywords fbw = .true., eliashberg = .true., laniso = .true., and limag = .true. in the EPW input file.

The anisotropic FBR Migdal-Eliashberg equations take the following form:

$$Z_{n\mathbf{k}}(i\omega_j) = 1 + \frac{T}{\omega_j N_F} \sum_{mj'} \int \frac{d\mathbf{q}}{\Omega_{BZ}} \frac{\omega_{j'} Z_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})}{\theta_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})} \lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_j - \omega_{j'})$$

$$\chi_{n\mathbf{k}}(i\omega_{j}) = \frac{-T}{N_{F}} \sum_{mj'} \int \frac{d\mathbf{q}}{\Omega_{BZ}} \frac{\varepsilon_{m\mathbf{k}'} - \mu_{F} + \chi_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})}{\theta_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})} \lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_{j} - \omega_{j'})$$

$$\phi_{n\mathbf{k}}(i\omega_{j}) = \frac{T}{N_{F}} \sum_{mj'} \int \frac{d\mathbf{q}}{\Omega_{BZ}} \frac{\phi_{m\mathbf{k}'}(i\omega_{j'})}{\theta_{m\mathbf{k}+\mathbf{q}}(i\omega_{j'})} \left[\lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_{j} - \omega_{j'}) - \mu_{c}^{*}\right] \tag{16}$$

where  $\lambda_{n\mathbf{k},m\mathbf{k}+\mathbf{q}}(\omega_j-\omega_{j'})$  is the anisotropic electron-phonon coupling strength. The superconducting gap is defined in terms of the renormalization function and the order parameter as:  $\Delta_{n\mathbf{k}}(i\omega_j) = \phi_{n\mathbf{k}}(i\omega_j)/Z_{n\mathbf{k}}(i\omega_j)$ . The semiempirical Coulomb parameter  $\mu_c^*$  is provided as an input varible muc.

This set of equations is supplemented with an equation for the electron number  $N_e$  which determines the chemical potential  $\mu_F$  if muchem = .true. is set in the EPW calculation.

$$N_{\rm e} = \sum_{n} \int \frac{d\mathbf{k}}{\Omega_{\rm BZ}} \left( 1 - 2T \sum_{j} \frac{\varepsilon_{n\mathbf{k}} - \mu_{\rm F} + \chi_{n\mathbf{k}}(i\omega_{j})}{\theta_{n\mathbf{k}}(i\omega_{j})} \right)$$
(17)

Here,  $N_{
m e}$  is the number of electrons per unit cell.

```

▶ 11th step: To compare the results of the superconducting gap with those from the previous FSR calculation, follow the steps 5 and 6 above. You can use the gnuplot scripts fig7-FBW.plt and fig9-FBW.plt.

#### Notes on input variables:

• ephwrite = .true. does not work with random k or q grids and requires nkf1, nkf2, nkf3 to be multiple of nqf1, nqf2, nqf3.

- mp\_mesh\_k = .true. specifies that only the irreducible points for the dense k grid are used. This significantly decreases the computational cost when solving the anisotropic Migdal-Eliashberg equations.
- If the anisotropic Migdal-Eliashberg equations are solved in a separate run from the one in which the ephmatXX, freq, egnv, and ikmap files saved in prefix.ephmat directory were generated, the code requires to use the same number of CPUs as the number of ephmatXX files. If you forget this the code will stop with a message asking to use npool equal to the number of ephmatXX files.
- lpade = .true. requires limag = .true.
- lacon = .true. requires both limag = .true. and lpade = .true..
- wscut gives the upper limit (in eV) of the summation over the Matsubara frequencies on the imaginary axis in the Migdal-Eliashberg equations (limag = .true.). Note that the input variable wscut is ignored if the number of frequency points is given using the input variable nswi. In this case, the number of frequency points in the summation is the same irrespective of the temperature.
- temps = t1 t2 t3 ... define the list of temperatures at which the Migdal-Eliashberg equations are evaluated. Note that an evenly spaced temperature grids can also be defined using nstemp, temps = min.temp max.temp input variables.
- ullet If temperatures larger than the critical temperature  $T_{
  m c}$  estimated using the Allen-Dynes formula are specified in the input file a warning message is written in the output file. The code may stop when such a temperature is reached if the Migdal-Eliashberg equations do not have a solution at that point.
- muchem solve the anisotropic FBW ME eqs. with variable chemical potential.
- gridsamp = 0 generates a uniform Matsubara frequency grid (default).
- gridsamp = 1 generates a sparse Matsubara frequency grid.
- imag\_read works if limag = .true. and laniso = .true. and it allows the code to read from file the superconducting gap and renormalization function on the imaginary axis at specific temperature XX from file prefix.imag\_aniso\_XX. The temperature is specified as temps = XX (first temperature) in the EPW input file.
- imag\_read can be used to: (1) solve the anisotropic Migdal-Eliashberg equations on the imaginary axis at temperatures greater than XX using as a starting point the superconducting gap estimated at temperature XX. (2) obtain the solutions of the anisotropic Migdal-Eliashberg equations on the real axis with lpade = .true. or lacon = .true. starting from the imaginary axis solutions at temperature XX; (3) write to file theanisotropic superconducting gap on the Fermi surface in cube format at temperature XX for iverbosity = 2. The generated output files are prefix.imag\_aniso\_gap\_XX\_YY.cube, where YY is the band number within the chosen energy window during the EPW calculation.

# Restart options (this requires to use the same number of cores as in the original run):

Restart from an interrupted q-point while writing ephmatXX files.
 Required files: prefix.epmatwp, prefix.ukk, crystal.fmt, epwdata.fmt, vmedata.fmt (or dmedata.fmt), restart.fmt, and selecq.fmt (selecq.fmt only needed if selecqread = .true. otherwise it will be re-created).

#### Input setup:

```
ep_coupling = .true.
elph = .true.

epwwrite = .false.
epwread = .true. ! read *.epmatwp and *.fmt files

wannierize = .false. ! read *.ukk file
ephwrite = .true.
```

2. Restart by reading ephmatXX files.

Required files: prefix.ephmat directory (which contains egnv, freq, ikmap, ephmatXX files), selecq.fmt, and crystal.fmt

Input setup:

```
ep_coupling = .false.
elph = .false.

epwwrite = .false.
epwread = .true.

wannierize = .false.
ephwrite = .false.
```
